

Introduction to OpenMP

Dirk Schmidl

IT Center, RWTH Aachen University

Member of the HPC Group

schmidl@itc.rwth-aachen.de

- **De-facto standard for Shared-Memory Parallelization.**
- **1997: OpenMP 1.0 for FORTRAN**
- **1998: OpenMP 1.0 for C and C++**
- **1999: OpenMP 1.1 for FORTRAN (errata)**
- **2000: OpenMP 2.0 for FORTRAN**
- **2002: OpenMP 2.0 for C and C++**
- **2005: OpenMP 2.5 now includes both programming languages.**
- **05/2008: OpenMP 3.0 release**
- **07/2011: OpenMP 3.1 release**
- **07/2013: OpenMP 4.0 release**

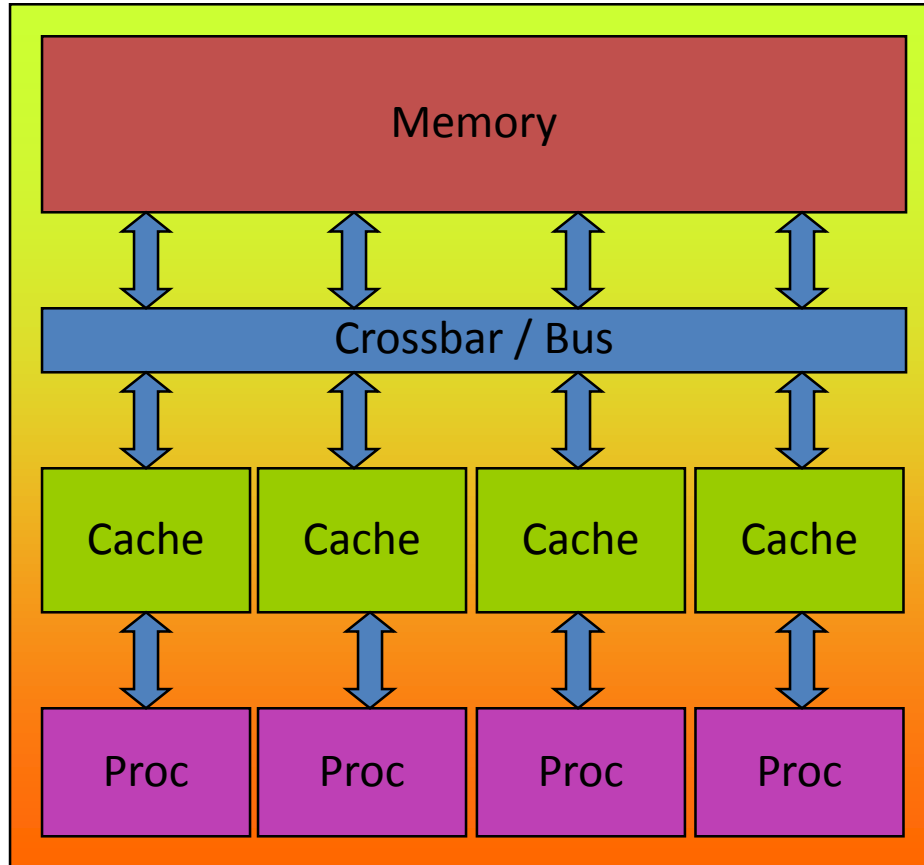

<http://www.OpenMP.org>

RWTH Aachen University is a member of the OpenMP Architecture Review Board (ARB) since 2006.

OpenMP Overview & Parallel Region

■ OpenMP: Shared-Memory Parallel Programming Model.

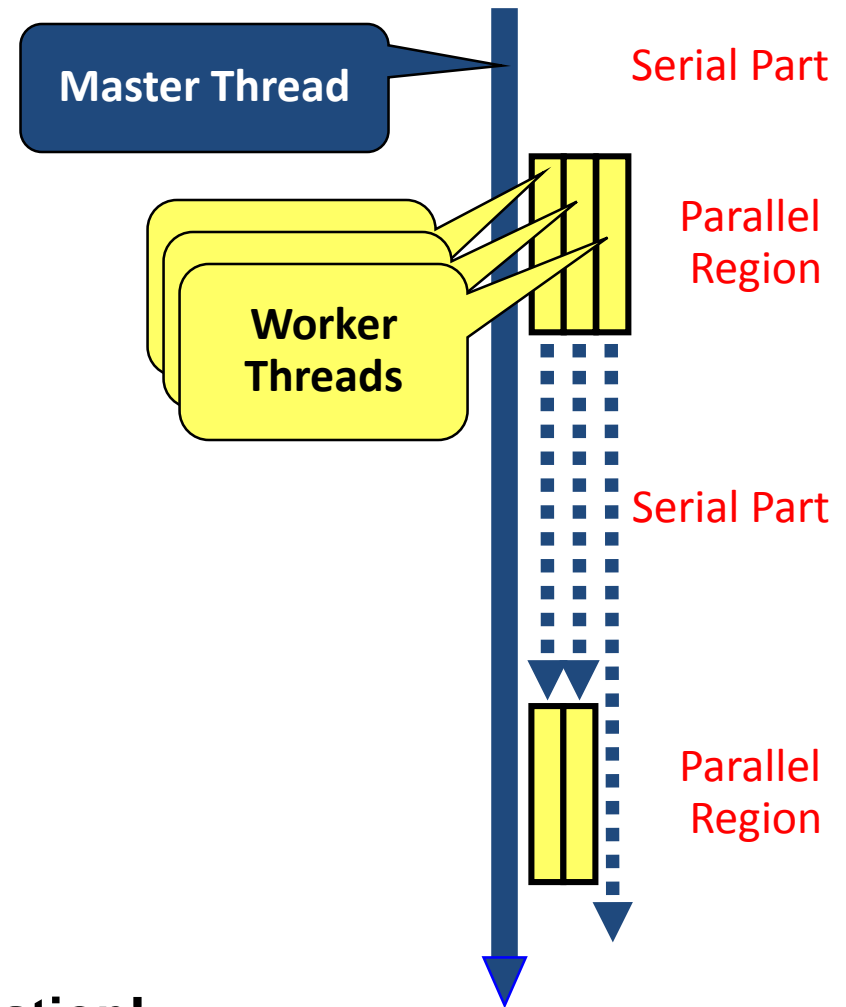

All processors/cores access a shared main memory.

Real architectures are more complex, as we will see later / as we have seen.

Parallelization in OpenMP employs multiple threads.

- OpenMP programs start with just one thread: The *Master*.
- *Worker* threads are spawned at *Parallel Regions*, together with the Master they form the *Team* of threads.
- In between Parallel Regions the Worker threads are put to sleep. The OpenMP *Runtime* takes care of all thread management work.
- Concept: *Fork-Join*.
- Allows for an incremental parallelization!

■ The parallelism has to be expressed explicitly.

C/C++

```
#pragma omp parallel
{
    ...
    structured block
    ...
}
```

Fortran

```
!$omp parallel
...
    structured block
...
$!omp end parallel
```

■ ***Structured Block***

- Exactly one entry point at the top
- Exactly one exit point at the bottom
- Branching in or out is not allowed
- Terminating the program is allowed
(abort / exit)

■ ***Specification of number of threads:***

- ▶ Environment variable:
OMP_NUM_THREADS=...
- ▶ Or: Via `num_threads` clause:
add `num_threads (num)` to the
parallel construct

Hello OpenMP World

Hello orphaned OpenMP World

- From within a shell, global setting of the number of threads:

```
export OMP_NUM_THREADS=4  
./program
```

- From within a shell, one-time setting of the number of threads:

```
OMP_NUM_THREADS=4 ./program
```

For Worksharing Construct

- If only the *parallel* construct is used, each thread executes the Structured Block.
- Program Speedup: *Worksharing*
- OpenMP's most common Worksharing construct: *for*

C/C++

```
int i;  
#pragma omp for  
for (i = 0; i < 100; i++)  
{  
    a[i] = b[i] + c[i];  
}
```

Fortran

```
INTEGER :: i  
!$omp do  
DO i = 0, 99  
    a[i] = b[i] + c[i];  
END DO
```

- Distribution of loop iterations over all threads in a Team.
- Scheduling of the distribution can be influenced.

- Loops often account for most of a program's runtime!

Pseudo-Code
Here: 4 Threads

Serial

```
do i = 0, 99  
  a(i) = b(i) + c(i)  
end do
```

Thread 1

```
do i = 0, 24  
  a(i) = b(i) + c(i)  
end do
```

Thread 2

```
do i = 25, 49  
  a(i) = b(i) + c(i)  
end do
```

Thread 3

```
do i = 50, 74  
  a(i) = b(i) + c(i)  
end do
```

Thread 4

```
do i = 75, 99  
  a(i) = b(i) + c(i)  
end do
```

Memory

Summing up Vector Elements

■ Can all loops be parallelized with `for`-constructs? No!

→ Simple test: If the results differ when the code is executed backwards, the loop iterations are not independent. BUT: This test alone is not sufficient:

C/C++

```
int i;  
#pragma omp parallel for  
for (i = 0; i < 100; i++)  
{  
    s = s + a[i];  
}
```

■ **Data Race:** If between two synchronization points at least one thread writes to a memory location from which at least one other thread reads, the result is not deterministic (race condition).

- **A *Critical Region* is executed by all threads, but by only one thread simultaneously (*Mutual Exclusion*).**

C/C++

```
#pragma omp critical (name)
{
    ... structured block ...
}
```

- **Do you think this solution scales well?**

C/C++

```
int i;
#pragma omp parallel for
for (i = 0; i < 100; i++)
{
    #pragma omp critical
    { s = s + a[i]; }
}
```

Data Scoping

- **Managing the Data Environment is the challenge of OpenMP.**
- **Scoping in OpenMP: Dividing variables in *shared* and *private*:**
 - *private*-list and *shared*-list on Parallel Region
 - *private*-list and *shared*-list on Worksharing constructs
 - General default is *shared* for Parallel Region, *firstprivate* for Tasks.
 - Loop control variables on *for*-constructs are *private*
 - Non-static variables local to Parallel Regions are *private*
 - *private*: A new uninitialized instance is created for each thread
 - *firstprivate*: Initialization with Master's value
 - *lastprivate*: Value of last loop iteration is written back to Master
 - Static variables are *shared*

■ Global / static variables can be privatized with the *threadprivate* directive

- One instance is created for each thread
 - Before the first parallel region is encountered
 - Instance exists until the program ends
 - Does not work (well) with nested Parallel Region
- Based on thread-local storage (TLS)
 - TlsAlloc (Win32-Threads), pthread_key_create (Posix-Threads), keyword `__thread` (GNU extension)

C/C++

```
static int i;  
#pragma omp threadprivate(i)
```

Fortran

```
SAVE INTEGER :: i  
!$omp threadprivate(i)
```

The Barrier Construct

■ OpenMP `barrier` (implicit or explicit)

→ Threads wait until all threads of the current *Team* have reached the barrier

C/C++

```
#pragma omp barrier
```

■ All worksharing constructs contain an implicit barrier at the end

Back to our bad scaling example

C/C++

```
int i;  
#pragma omp parallel for  
for (i = 0; i < 100; i++)  
{  
    #pragma omp critical  
    { s = s + a[i]; }  
}
```

It's your turn: Make It Scale!

```
#pragma omp parallel
```

```
{
```

```
#pragma omp for
```

```
  for (i = 0; i < 99; i++)
```

```
  {
```

```
      s = s + a[i];
```

```
  }
```

```
} // end parallel
```

```
do i = 0, 99  
  s = s + a(i)  
end do
```

```
do i = 0, 24  
  s = s + a(i)  
end do
```

```
do i = 25, 49  
  s = s + a(i)  
end do
```

```
do i = 50, 74  
  s = s + a(i)  
end do
```

```
do i = 75, 99  
  s = s + a(i)  
end do
```

- In a *reduction*-operation the operator is applied to all variables in the list. The variables have to be *shared*.

→ `reduction(operator:list)`

→ The result is provided in the associated reduction variable

C/C++

```
#pragma omp parallel for reduction(+:s)
for(i = 0; i < 99; i++)
{
    s = s + a[i];
}
```

→ Possible reduction operators with initialization value:

`+` (0), `*` (1), `-` (0),

`&` (~0), `|` (0), `&&` (1), `||` (0),

`^` (0), `min` (least number), `max` (largest number)

PI

Example: Pi (1/2)

```
double f(double x)
{
    return (4.0 / (1.0 + x*x));
}
```

```
double CalcPi (int n)
{
    const double fH = 1.0 / (double) n;
    double fSum = 0.0;
    double fX;
    int i;
```

```
#pragma omp parallel for
for (i = 0; i < n; i++)
{
    fX = fH * ((double)i + 0.5);
    fSum += f(fX);
}
return fH * fSum;
}
```

$$\pi = \int_0^1 \frac{4}{1+x^2}$$

Example: Pi (1/2)

```
double f(double x)
{
    return (4.0 / (1.0 + x*x));
}
```

```
double CalcPi (int n)
{
    const double fH  = 1.0 / (double) n;
    double fSum = 0.0;
    double fX;
    int i;

    #pragma omp parallel for private(fX,i) reduction(+:fSum)
    for (i = 0; i < n; i++)
    {
        fX = fH * ((double)i + 0.5);
        fSum += f(fX);
    }
    return fH * fSum;
}
```

$$\pi = \int_0^1 \frac{4}{1+x^2}$$

■ Results:

# Threads	Runtime [sec.]	Speedup
1	1.11	1.00
2		
4		
8	0.14	7.93

■ Scalability is pretty good:

- About 100% of the runtime has been parallelized.
- As there is just one parallel region, there is virtually no overhead introduced by the parallelization.
- Problem is parallelizable in a trivial fashion ...

Correctness Checking Tools

- **Data Race: the typical OpenMP programming error, when:**
 - two or more threads access the same memory location, and
 - at least one of these accesses is a write, and
 - the accesses are not protected by locks or critical regions, and
 - the accesses are not synchronized, e.g. by a barrier.
- **Non-deterministic occurrence: e.g. the sequence of the execution of parallel loop iterations is non-deterministic and may change from run to run**
- **In many cases *private* clauses, *barriers* or *critical regions* are missing**
- **Data races are hard to find using a traditional debugger**
 - Use the *Intel Inspector XE*

■ Detection of

- Memory Errors
- Dead Locks
- Data Races

■ Support for

- Linux (32bit and 64bit) and Windows (32bit and 64bit)
- WIN32-Threads, Posix-Threads, Intel Threading Building Blocks and OpenMP

```
double f(double x)
{
    return (4.0 / (1.0 + x*x));
}
```

```
double CalcPi (int n)
{
    const double fH  = 1.0 / (double) n;
    double fSum = 0.0;
    double fX;
    int i;

    #pragma omp parallel for private(fX,i) reduction(+:fSum)
    for (i = 0; i < n; i++)
    {
        fX = fH * ((double)i + 0.5);
        fSum += f(fX);
    }
    return fH * fSum;
}
```

$$\pi = \int_0^1 \frac{4}{1+x^2}$$

```
double f(double x)
{
    return (4.0 / (1.0 + x*x));
}

double CalcPi (int n)
{
    const double fH  = 1.0 / (double) n;
    double fSum = 0.0;
    double fX;
    int i;

    #pragma omp parallel for private(fX,i) reduction(+:fSum)
    for (i = 0; i < n; i++)
    {
        fX = fH * ((double)i + 0.5);
        fSum += f(fX);
    }
    return fH * fSum;
}
```

What if we
would have
forgotten this?

Threading Error Analysis Modes

1. Detect Deadlocks
2. Detect Deadlocks and Data Races
3. Locate Deadlocks and Data Races

more details,
more overhead

Inspector XE – Results

- 1 detected problems
- 2 filters
- 3 code location

The missing reduction
is detected.

The screenshot shows the Intel Inspector XE 2011 interface. The top bar indicates the target is 'r001ti3'. The main window is titled 'Locate Deadlocks and Data Races'. The 'Problems' pane on the left shows a single problem, 'P1', which is a 'Data race' in 'pi.c' at 'pi.exe', with a state of 'New'. The 'Code Locations' pane below it shows two locations, 'X1' (Read) and 'X2' (Write), both at 'pi.c:71' in the 'CalcPi' function of 'pi.exe'. The code snippet for both locations is:

```
69 {  
70     fX = fH * ((double)i + 0.5);  
71     fSum += f(fX);  
72 }  
73 return fH * fSum;
```

The 'Filters' pane on the right shows the following counts:

Severity	Count
Error	1 item(s)

Problem	Count
Data race	1 item(s)

Source	Count
pi.c	1 item(s)

Module	Count
pi.exe	1 item(s)

State	Count
New	1 item(s)

Suppressed	Count
Not suppressed	1 item(s)

Investigated	Count
Not investigated	1 item(s)

Yellow circles with numbers 1, 2, and 3 are overlaid on the image to highlight the detected problem, the filters, and the code location, respectively.

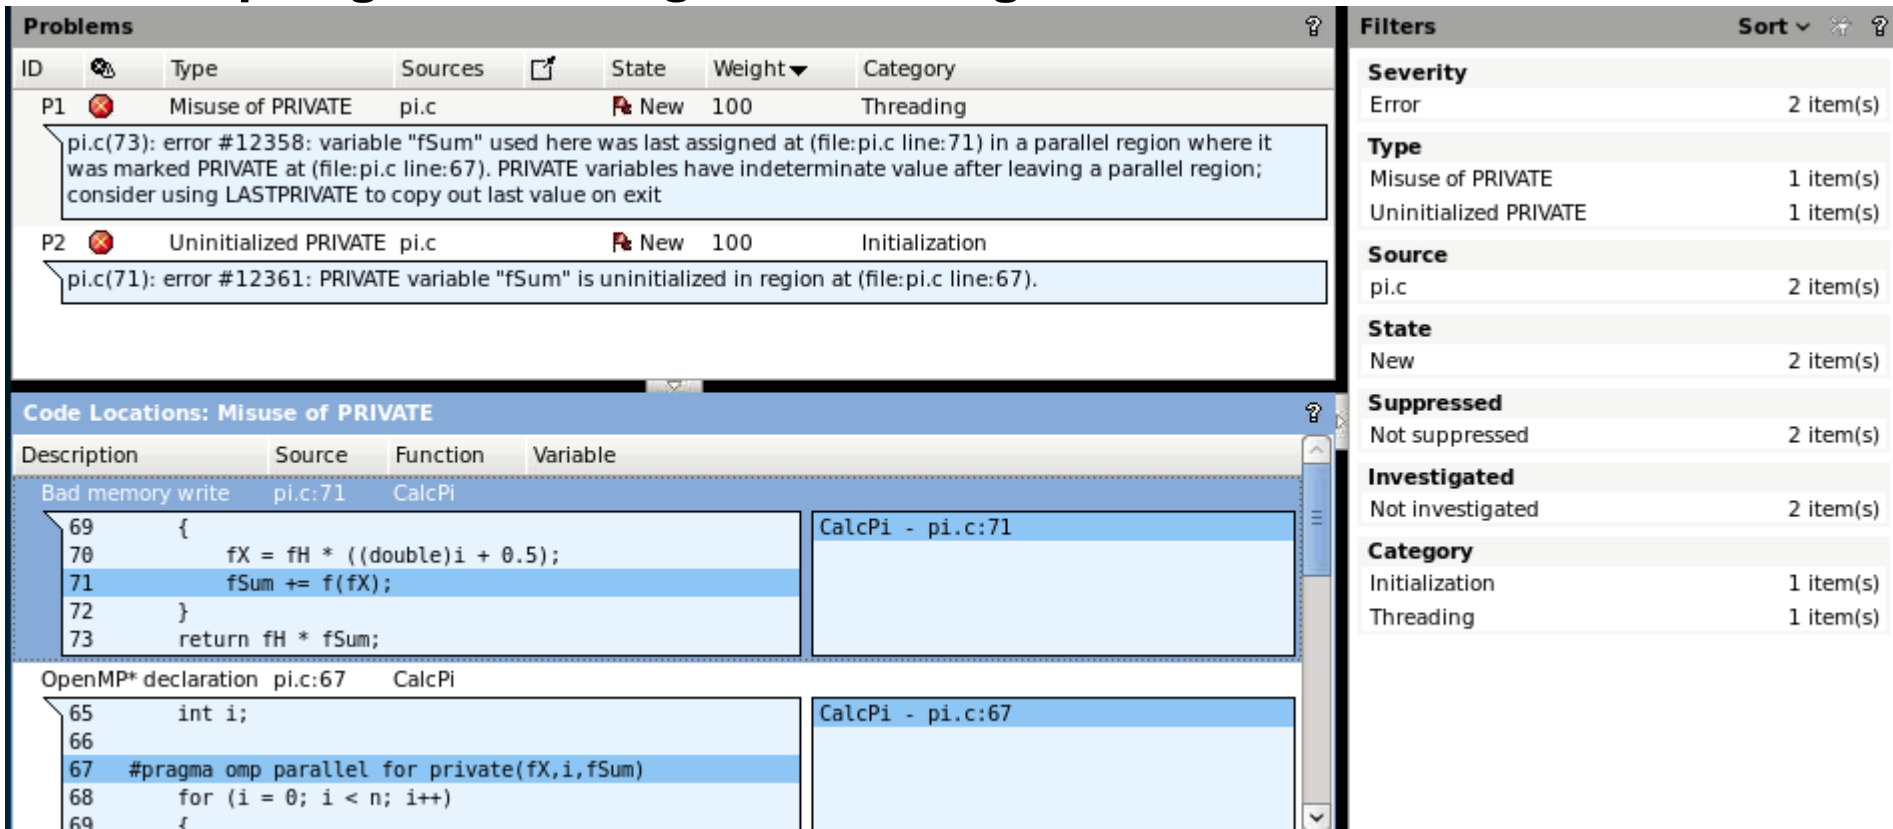

```
double f(double x)
{
    return (4.0 / (1.0 + x*x));
}
```

```
double CalcPi (int n)
{
    const double fH  = 1.0 / (double) n;
    double fSum = 0.0;
    double fX;
    int i;
```

```
#pragma omp parallel for private(fX,i,fSum)
    for (i = 0; i < n; i++)
    {
        fX = fH * ((double)i + 0.5);
        fSum += f(fX);
    }
    return fH * fSum;
}
```

What if we just
made the
variable private?

- At runtime no Error is detected!
- Compiling with the argument “-diag-enable sc-full” delivers:

The screenshot displays the Inspector XE interface with two main panels: 'Problems' and 'Code Locations: Misuse of PRIVATE'.

Problems Panel:

ID	Type	Sources	State	Weight	Category
P1	Misuse of PRIVATE	pi.c	New	100	Threading
pi.c(73): error #12358: variable "fSum" used here was last assigned at (file:pi.c line:71) in a parallel region where it was marked PRIVATE at (file:pi.c line:67). PRIVATE variables have indeterminate value after leaving a parallel region; consider using LASTPRIVATE to copy out last value on exit					
P2	Uninitialized PRIVATE	pi.c	New	100	Initialization
pi.c(71): error #12361: PRIVATE variable "fSum" is uninitialized in region at (file:pi.c line:67).					

Code Locations: Misuse of PRIVATE Panel:

Description	Source	Function	Variable
Bad memory write	pi.c:71	CalcPi	
<pre>69 { 70 fX = fH * ((double)i + 0.5); 71 fSum += f(fX); 72 } 73 return fH * fSum;</pre>			
OpenMP* declaration	pi.c:67	CalcPi	
<pre>65 int i; 66 67 #pragma omp parallel for private(fX,i,fSum) 68 for (i = 0; i < n; i++) 69 {</pre>			

Filters Panel:

Severity	Count
Error	2 item(s)
Type	Count
Misuse of PRIVATE	1 item(s)
Uninitialized PRIVATE	1 item(s)
Source	Count
pi.c	2 item(s)
State	Count
New	2 item(s)
Suppressed	Count
Not suppressed	2 item(s)
Investigated	Count
Not investigated	2 item(s)
Category	Count
Initialization	1 item(s)
Threading	1 item(s)

- At compile-time this error can be found!

Single and Master Construct

C/C++

```
#pragma omp single [clause]  
... structured block ...
```

Fortran

```
!$omp single [clause]  
... structured block ...  
!$omp end single
```

- The **single** construct specifies that the enclosed structured block is executed by only one thread of the team.

→ It is up to the runtime which thread that is.

- Useful for:

→ I/O

→ Memory allocation and deallocation, etc. (in general: setup work)

→ Implementation of the single-creator parallel-executor pattern as we will see now...

C/C++

```
#pragma omp master[clause]  
... structured block ...
```

Fortran

```
!$omp master[clause]  
... structured block ...  
!$omp end master
```

- The `master` construct specifies that the enclosed structured block is executed only by the master thread of a team.
- Note: The master construct is no worksharing construct and does not contain an implicit barrier at the end.

Section and Ordered Construct

■ How would you parallelize this code?

```
void traverse (Tree *tree)
{
    if (tree->left)    traverse(tree->left) ;

    if (tree->right)    traverse(tree->right) ;

    process (tree) ;
}
```

■ One option: Use OpenMP's parallel sections.

C/C++

```
#pragma omp sections [clause]
{
    #pragma omp section
    ... structured block ...
    #pragma omp section
    ... structured block ...
    ...
}
```

Fortran

```
!$omp sections [clause]
!$omp section
... structured block ...
!$ omp section
... structured block ...
...
!$omp end sections
```

- The **sections** construct contains a set of structured blocks that are to be distributed among and executed by the team of threads.

How to parallelize a Tree Traversal?!

■ How would you parallelize this code?

```
void traverse (Tree *tree)
{
#pragma omp parallel sections
{
#pragma omp section
    if (tree->left)    traverse(tree->left) ;
#pragma omp section
    if (tree->right)   traverse(tree->right) ;
} // end omp parallel
    process(tree) ;
```

Nested Parallel Regions

Barrier here!

We will later see how this can be done with tasks in a better way.

→ Not always well supported (how many threads to be used?)

- **Allows to execute a structured block within a parallel loop in sequential order**

→ In addition, an `ordered` clause has to be added to the `for` construct which any *ordered* construct may occur

```
#pragma omp parallel for ordered
for (i=0 ; i<10 ; i++){
    ...
    #pragma omp ordered
    {
        ...
    }
    ...
}
```

- **Use Cases:**

→ Can be used e.g. to enforce ordering on printing of data

→ May help to determine whether there is a data race

Runtime Library

■ C and C++:

- If OpenMP is enabled during compilation, the preprocessor symbol `_OPENMP` is defined. To use the OpenMP runtime library, the header `omp.h` has to be included.
- `omp_set_num_threads(int)`: The specified number of threads will be used for the parallel region encountered next.
- `int omp_get_num_threads`: Returns the number of threads in the current team.
- `int omp_get_thread_num()`: Returns the number of the calling thread in the team, the Master has always the id 0.

■ Additional functions are available, e.g. to provide locking functionality.

Tasking

Recursive approach to compute Fibonacci

```
int main(int argc,  
        char* argv[])  
{  
    [...]  
    fib(input);  
    [...]  
}
```

```
int fib(int n)    {  
    if (n < 2) return n;  
    int x = fib(n - 1);  
    int y = fib(n - 2);  
    return x+y;  
}
```

- On the following slides we will discuss three approaches to parallelize this recursive code with Tasking.

C/C++

```
#pragma omp task [clause]  
... structured block ...
```

Fortran

```
!$omp task [clause]  
... structured block ...  
!$omp end task
```

■ Each encountering thread/task creates a new Task

- Code and data is being packaged up
- Tasks can be nested
 - Into another Task directive
 - Into a Worksharing construct

■ Data scoping clauses:

- `shared(list)`
- `private(list)` `firstprivate(list)`
- `default(shared | none)`

- **Some rules from *Parallel Regions* apply:**
 - Static and Global variables are shared
 - Automatic Storage (local) variables are private

- **If shared scoping is not derived by default:**
 - Orphaned Task variables are `firstprivate` by default!
 - Non-Orphaned Task variables inherit the `shared` attribute!
 - Variables are `firstprivate` unless `shared` in the enclosing context

First version parallelized with Tasking (omp-v1)

```
int main(int argc,
        char* argv[])
{
    [...]
    #pragma omp parallel
    {
        #pragma omp single
        {
            fib(input);
        }
    }
    [...]
}
```

```
int fib(int n)    {
    if (n < 2) return n;
    int x, y;
    #pragma omp task shared(x)
    {
        x = fib(n - 1);
    }
    #pragma omp task shared(y)
    {
        y = fib(n - 2);
    }
    #pragma omp taskwait
    return x+y;
}
```

- **Only one Task / Thread enters `fib()` from `main()`, it is responsible for creating the two initial work tasks**
- **Taskwait is required, as otherwise `x` and `y` would be lost**

- T1 enters fib(4)
- T1 creates tasks for fib(3) and fib(2)
- T1 and T2 execute tasks from the queue
- T1 and T2 create 4 new tasks
- T1 - T4 execute tasks

Task Queue

- T1 enters fib(4)
- T1 creates tasks for fib(3) and fib(2)
- T1 and T2 execute tasks from the queue
- T1 and T2 create 4 new tasks
- T1 - T4 execute tasks
- ...

■ Overhead of task creation prevents better scalability!

- **Improvement: Don't create yet another task once a certain (small enough) n is reached**

```
int main(int argc,
        char* argv[])
{
    [...]
    #pragma omp parallel
    {
        #pragma omp single
        {
            fib(input);
        }
    }
    [...]
}
```

```
int fib(int n)    {
    if (n < 2) return n;
    int x, y;
    #pragma omp task shared(x) \
        if(n > 30)
    {
        x = fib(n - 1);
    }
    #pragma omp task shared(y) \
        if(n > 30)
    {
        y = fib(n - 2);
    }
    #pragma omp taskwait
    return x+y;
}
```

- Speedup is ok, but we still have some overhead when running with 4 or 8 threads

Speedup of Fibonacci with Tasks

- **Improvement: Skip the OpenMP overhead once a certain n is reached (no issue w/ production compilers)**

```
int main(int argc,
        char* argv[])
{
    [...]
    #pragma omp parallel
    {
        #pragma omp single
        {
            fib(input);
        }
    }
    [...]
}
```

```
int fib(int n)    {
    if (n < 2) return n;
    if (n <= 30)
        return serfib(n);
    int x, y;
    #pragma omp task shared(x)
    {
        x = fib(n - 1);
    }
    #pragma omp task shared(y)
    {
        y = fib(n - 2);
    }
    #pragma omp taskwait
    return x+y;
}
```

■ Everything ok now 😊

Speedup of Fibonacci with Tasks

Data Scoping Example (1/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a:
            // Scope of b:
            // Scope of c:
            // Scope of d:
            // Scope of e:

        }
    }
}
```

Data Scoping Example (2/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a: shared
            // Scope of b:
            // Scope of c:
            // Scope of d:
            // Scope of e:

        }
    }
}
```

Data Scoping Example (3/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a: shared
            // Scope of b: firstprivate
            // Scope of c:
            // Scope of d:
            // Scope of e:
        }
    }
}
```

Data Scoping Example (4/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a: shared
            // Scope of b: firstprivate
            // Scope of c: shared
            // Scope of d:
            // Scope of e:
        }
    }
}
```

Data Scoping Example (5/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a: shared
            // Scope of b: firstprivate
            // Scope of c: shared
            // Scope of d: firstprivate
            // Scope of e:

        }
    }
}
```

Data Scoping Example (6/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a: shared
            // Scope of b: firstprivate
            // Scope of c: shared
            // Scope of d: firstprivate
            // Scope of e: private
        }
    }
}
```

Hint: Use default(none) to be forced to think about every variable if you do not see clear.

Data Scoping Example (7/7)

```
int a = 1;
void foo()
{
    int b = 2, c = 3;
    #pragma omp parallel shared(b)
    #pragma omp parallel private(b)
    {
        int d = 4;
        #pragma omp task
        {
            int e = 5;

            // Scope of a: shared,          value of a: 1
            // Scope of b: firstprivate,    value of b: 0 / undefined
            // Scope of c: shared,          value of c: 3
            // Scope of d: firstprivate,    value of d: 4
            // Scope of e: private,        value of e: 5

        }
    }
}
```

■ OpenMP `barrier` (implicit or explicit)

- All tasks created by any thread of the current *Team* are guaranteed to be completed at barrier exit

C/C++

```
#pragma omp barrier
```

■ Task barrier: `taskwait`

- Encountering Task suspends until child tasks are complete
 - Only direct childs, not descendants!

C/C++

```
#pragma omp taskwait
```

■ Task Synchronization explained:

```
#pragma omp parallel num_threads(np)
{
    #pragma omp task
        function_A();
    #pragma omp barrier
    #pragma omp single
    {
        #pragma omp task
            function_B();
    }
}
```

np Tasks created here, one for each thread

All Tasks guaranteed to be completed here

1 Task created here

B-Task guaranteed to be completed here

More Environment Variables

- **OMP_NUM_THREADS:** Controls how many threads will be used to execute the program.
- **OMP_SCHEDULE:** If the schedule-type *runtime* is specified in a schedule clause, the value specified in this environment variable will be used.
- **OMP_DYNAMIC:** The OpenMP runtime is allowed to smartly guess how many threads might deliver the best performance. If you want full control, set this variable to *false*.
- **OMP_NESTED:** Most OpenMP implementations require this to be set to *true* in order to enable nested Parallel Regions. Remember: Nesting Worksharing constructs is not possible.

■ Define interaction with system environment:

- Env. Var. OMP_MAX_NESTED_LEVEL + API functions
 - Controls the maximum number of active parallel regions
- Env. Var. OMP_THREAD_LIMIT + API functions
 - Controls the maximum number of OpenMP threads
- Env. Var. OMP_STACKSIZE
 - Controls the stack size of child threads
- Env. Var. OMP_WAIT_POLICY
 - Control the thread idle policy:
 - active: Good for dedicated systems (e.g. in batch mode)
 - passive: Good for shared systems
